✓ Conclusion
Aim of the study

- **State of the art:**
  Epidemiological studies show an association between the presence of birch, grass and ragweed pollen in the air and the consumption of anti-allergic drugs and hospitalizations for asthma.

- **Aim of the study:**
  The aim of the study was to show the relationships between birch, grass and ragweed pollen concentrations and intensity of symptoms in patients with hay fever, on a significant number of subjects, using adequate statistical tools.
Materials and methods (1)

3 panel studies were conducted:
- Allergy sufferers to birch pollen in 2010
- Allergy sufferers to grass pollen in 2010
- Allergy sufferers to ragweed pollen in 2009 and 2010

**Exposure: Metrology and pollen data:**
Daily birch, grass and ragweed pollen concentrations were obtained from the National Aerobiological Network Survey (RNSA). Measurements were made with Hirst-type pollen traps (fig 1). Pollen grains were identified and counted by trained analysts (fig 2).
Health impact:
The patients were asked to complete a diary with ocular, nasal, and bronchial symptoms during the pollen seasons of ragweed, birch and grass.

They were asked to record their own symptoms each evening. The severity of ocular, nasal and bronchial symptoms were recorded on scale from 0 to 3 (0 = no symptoms, 1 = light symptoms, 2 = moderate symptoms, 3 = severe symptoms).

Quality of life:
The quality of life was also a variable assessed by patients on a scale from 0 (bad quality of life) to 10 (good quality of life).
The patients selected for the study come from different cities of France and Switzerland:
- For **birch**: Nantes, Angers, Tours, Paris, Amiens, Rouen, Dijon, Chalon sur Saône, Clermont Ferrand, Roussillon, Chambéry and Genève.
- For **grass**: Nantes, Angers, Tours, La Rochelle, Paris, Amiens, Rouen, Dijon, Chalon sur Saône, Clermont Ferrand, Chambéry and Genève.
- For **ragweed**: Avignon, Grenoble, Lyon, Saint-Etienne, Nevers, Genève.

(Map birch)                                       (Map grass)                             (Map ragweed)

RESULTS
Results – Exposure – Birch and grass panels

(Birch 2010)  (Grass 2010)
Results – Exposure – Ragweed panel
Results – Health impact – Birch panel

**Table 1** shows that during the whole birch pollination, for each increase of 10 grains/m³, the percentage of patients with moderate to severe symptoms also increased (odds ratio, standard deviation.)
These graphs present the shape of the pollens-symptoms relation from the GAMM models for respectively nasal, ocular and bronchial symptoms for the grass panel.
Symptoms/Years | 2009 | 2010
---|---|---
Ocular symptoms | 1.324 | 1.049
Respiratory symptoms | 1.139 | 1.027
Nasal symptoms | 1.426 | 1.247

In 2009, there was an average increase of 32.4% in the prevalence of moderate to severe ocular symptoms and 13.9% for respiratory symptoms and 42.6% for nasal symptoms for an increase of 10 grains/m³ pollen. This increase was lower in 2010.
Results – Quality of life – Ragweed panel

For each increase of 10 grains/m³, the quality of life, measured on a scale of 0 to 10, decreased significantly (0.099 point in 2009 and 0.020 points in 2010). There was a significant and negative relationship between quality of life and concentrations of ragweed pollen, and this relationship was stronger in 2009 (Graphs 1 and 2).
Conclusion

**Conclusion Birch:**
- The clinical response in patients sensitized to natural exposure of birch varies during the pollen season. There is a threshold followed by a linear relationship up to a saturation plateau. The dose-response relationship is nonlinear for nasal, ocular and respiratory symptoms with an increase of symptoms in relation to the increase of pollen followed by a plateau.

**Conclusion grass:**
- The clinical response in patients sensitized to grasses varies during the pollen season. With regard to nasal and ocular symptoms, there is a priming effect and co-priming early in the season without a threshold, then a linear response up to a plateau.

**Conclusion ragweed:**
- The increase of ragweed pollen causes a greater increase of ocular, nasal and respiratory symptoms in 2009 than in 2010. Quality of life deteriorates significantly when ragweed pollen increases. To our knowledge, this is the first epidemiological study that enables the quantification between ragweed pollen and health effects.

One of the main strengths of this study is its statistical power, because of repeated measurements and is huge number of pollinosis patients (200).
Thank you for your attention
